Asymmetric Capacitated Vehicle Routing Problem

Outline

ACVRP

SR-GCWS-CS

Adaptation to
the Asymmetric

Results

- A set of customer demands have to be served
- A fleet of homogeneous fleet
- Each customer is supplied by a single vehicle
- The travel cost represents asymmetric distances or travelling times
- Minimizing travel cost

Example

Solution using minimum distances and real itineraries

- Laporte, G., Mercure, H., and Nobert, Y. (1986).
An exact algorithm for the asymmetrical capacitated vehicle-routing problem. *Networks*, 16(1):33–46.
- Fischetti, M., Toth, P., and Vigo, D. (1994).
A branch-and-bound algorithm for the capacitated vehicle-routing problem on directed-graphs. *Operations Research*, 42(5):846–859.
- Clarke, G. and Wright, J. (1964).
Scheduling of vehicles from central depot to number of delivery points. *Operations Research*, 12(4):568–581.
- Fisher, M. and Jaikumar, R. (1981).
A generalized assignment heuristic for vehicle-routing. *Networks*, 11(2):109–124.

Adaptation to
the Asymmetric

Results

- 1 Asymmetric Capacitated Vehicle Routing Problem
- 2 On the use of Monte Carlo simulation, cache and splitting techniques to improve the Clarke and Wright savings heuristics
- 3 Adaptation to the Asymmetric
- 4 Results

Clarke and Wright Savings

- Best-known heuristics for solving the VRP
- Great simplicity and fast implementation
- Baseline scenario in which each customer is supplied by a separate vehicle
- The saving supplying to customers i and j for the same vehicle are: $S_{ij} = d_{0i} + d_{0j} - d_{ij}$
- It always chooses the edge with the highest savings value if the constraints are not violated

Simulation in Routing via the Generalized Clarke and Wright Savings heuristic

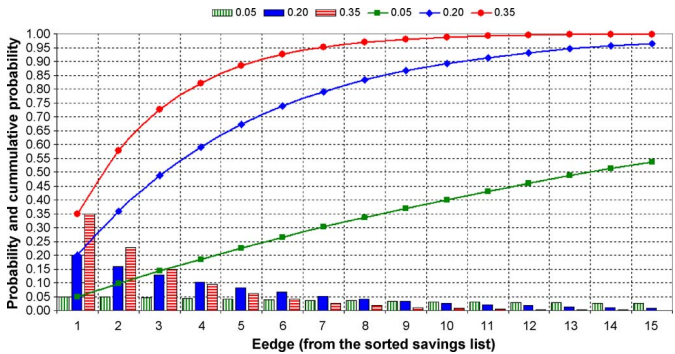

Fig. 1. Effects of the chosen parameter on the geometric distribution.

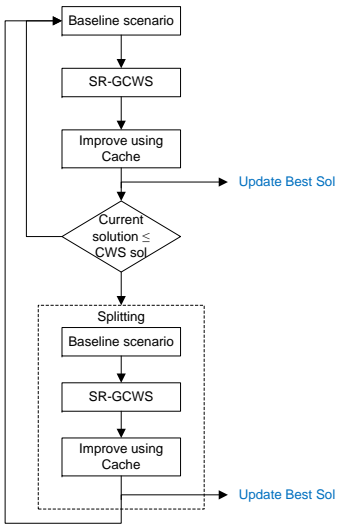

Each time a new edge must be selected, a quasi-geometric distribution assigns a random value at each edge assigning exponentially diminishing probabilities to each eligible edge according to its position inside the sorted saving list.

Splitting policies

Divide the original set of nodes into disjoint subsets and then to solve each of these subsets by applying the same methodology described before.

**Adaptation to
the Asymmetric**

Results

- 1 Asymmetric Capacitated Vehicle Routing Problem
- 2 On the use of Monte Carlo simulation, cache and splitting techniques to improve the Clarke and Wright savings heuristics
- 3 Adaptation to the Asymmetric**
- 4 Results

Savings

- The saving supplying to customers i and j for the same vehicle are: $S_{ij} = \hat{d}_{0i} + \hat{d}_{0j} - \hat{d}_{ij}$
- $\hat{d}_{0i} = \frac{d_{0i} + d_{i0}}{2}$

Outline

ACVRP

SR-GCWS-CS

Adaptation to
the Asymmetric

Results

Savings

- The saving supplying to customers i and j for the same vehicle are: $S_{ij} = \hat{d}_{0i} + \hat{d}_{0j} - \hat{d}_{ij}$
- $\hat{d}_{0i} = \frac{d_{0i} + d_{i0}}{2}$

Savings

- The saving supplying to customers i and j for the same vehicle are: $S_{ij} = \hat{d}_{0i} + \hat{d}_{0j} - \hat{d}_{ij}$
- $\hat{d}_{0i} = \frac{d_{0i} + d_{i0}}{2}$

Improve using Cache

Outline

ACVRP

SR-GCWS-CS

Adaptation to
the Asymmetric

Results

- Improve nodes order trying to sort its nodes in a more efficient way by eliminating possible knots in the current route.
- Compare with its reverse route.
- Check if it exists already a cached route covering the same set of nodes.

- 2 On the use of Monte Carlo simulation, cache and splitting techniques to improve the Clarke and Wright savings heuristics
- 3 Adaptation to the Asymmetric
- 4 Results**

Results

Outline

ACVRP

SR-GCWS-CS

Adaptation to
the Asymmetric

Results

- 20 asymmetric CVRP instances have been used
- With 50 or 100 customers
- A fleet from 2 to 7 vehicles
- 10 random seeds
- 1 minute of Elapsed Time
- Processor: Intel Pentium Dual CPU 2.40 GHz with 3.25 GB Ram
